  - Safety injection device evaluation form
Introduction
The process for giving an injection includes some basic steps. This manual divides the injection process into four categories. Upon completion of this booklet, the participant should have an understanding of:

Selection
List factors that need to be considered when selecting a syringe and needle for an injection.

Preparation
Describe the following components of medication preparation, assembling, preparing and checking.

Administration
List the medication volumes that can safely be injected into the following areas: intramuscular, subcutaneous and intradermal.

Disposal
Describe the four safety performance criteria for sharps disposal containers.

This booklet is intended to educate healthcare workers with information on how to prepare and administer skin injections safely and correctly.

The basic topics, standard for all injections, discussed in the following pages are:

- Assessment of patient – This manual assumes that the healthcare worker has basic knowledge and education on proper patient assessment.
- Type of injection
- Site selection
- Selection and assembly of supplies and devices
- Injection administration
- Safe disposal of waste materials
Selecting the devices

There are many different syringes and needles suiting many different procedures. It is important to choose the needles and syringes carefully according to the type of injection to be administered. For example, the length and gauge of needle and type of syringe must be suitable for the injection site, viscosity and volume of medication. The BMI, age and condition of the patient are other key factors in the selection process.
The anatomy of the BD needle

Bevel

The sharpened angular tip at the end of the needle. There are typically four types of bevels used for skin injections.

**Regular bevel:** The most common bevel, used for a vast majority of applications. Typically used for intramuscular and subcutaneous injections.

**Short bevel:** Used for specialty applications such as arterial blood gas sampling and nerve blocks.

**Intradermal bevel:** This needle bevel is used primarily for skin testing (e.g., allergy tests).

**5-bevel:** The two additional bevels create a flatter, thinner surface that is perceived to have less pain.

Hub

Allows user to attach the needle to a syringe by either a luer lock or a luer slip connection. All safety-engineered needles are color coded to denote the gauge of the needle. (See chart on pages 14 and 15.)

Needle

Most needles are made of stainless steel, which is siliconized to allow easier penetration force. Available in different lengths and gauges to suit individual clinical and patient needs.

**There are three types of needle walls:**

**Regular wall:** This is the most common wall thickness. The thickness of the steel wall minimizes flexing when the needle is inserted into a vial stopper or patient.

**Thin wall:** As shown in the diagram, the thin wall needle has a narrower steel wall, allowing a greater volume of fluid to pass through it. The flow rate is typically equivalent to that of a regular wall needle one gauge larger. This is especially important with very thin needles.

**Extra thin wall:** This has the thinnest steel wall, designed to increase the benefits of the thin wall needle.

Safety mechanism

Designed to protect the user from accidental needlestick injuries. Safety technology for injection needles include retracting syringes, shielding needles and sliding sleeve syringes.

* Study was not conducted on all needle sizes.
Luer lock tip

Generally used for injections requiring a secure connection of the syringe to another device. The tip is threaded for a “locking” fit and is compatible with a variety of needles, catheters and other devices.

Luer slip tip

A friction-fit connection that requires the clinician to insert the tip of the syringe into the needle hub or other luer connection in a push-and-twist manner. This will ensure a connection that is less likely to detach. Simply sliding the attaching device onto the syringe tip may not ensure a secure fitting.

Eccentric luer slip tip

Allows for work requiring closer proximity to the skin. Generally used for venipunctures and aspiration of fluids. (Also see luer slip instructions above.)

Catheter tip

Used for flushing (cleaning) catheters, gastrostomy tubes and other devices. Insert catheter tip securely into catheter or gastrostomy tube. If leakage occurs, refer to your facility’s guidelines.

Permanently attached needle

Most commonly found in insulin and tuberculin syringes. Permanently attached needles, also known as integral needles, reduce the amount of medication waste.

The anatomy of the syringe

1. **Stopper:** Prevents leakage of medication around the plunger, and acts as an indicator for measuring the syringe’s contents (see diagram).

2. **Scale markings:** Scale markings are typically in milliliter (mL) units. On insulin syringes, however, graduations are displayed in “units” based on the insulin concentration prescribed. (Example: U-100 means 100 units of insulin suspended within 1 mL of fluid. A 3/10 mL insulin syringe will accommodate up to 30 units when using U-100 insulin.)

3. **Barrel:** Reservoir for holding liquid, clearly graduated to allow accurate and visual measurement of the syringe’s contents.

4. **Flanges:** The “wings” that extend out from the side of the syringe barrel that provide an area or surface for the index finger and middle finger to grasp during aspiration or administration.

5. **Plunger rod:** A piston-like device inside the barrel.

6. **Thumb press:** Area where clinician presses to push plunger rod down into barrel to expel contents.
The anatomy of the medication pen

### Types of pen needles
- Conventional pen needles (without safety engineering) used by self-injecting patients. Pen needles should be used once.1

- Safety-engineered pen needles used by healthcare providers (this example shows protective shields at both ends of the pen needle after use).

### Important:

#### Pen injector
- Pen injectors can be used for one person only—“one pen, one patient.”

- Pen injectors, often the size and shape of a large marker, carry medication in self-contained cartridges. The most commonly used pens contain insulin. Intended primarily for self-injection, medication pens are now also used in healthcare settings.

- Another type of pen injectors is single use with a preattached needle.

#### Insulin pens
- Insulin pens: After attaching pen needle, the needle needs to be always primed following the manufacturer’s directions.

- Insulin pens fall into one of two groups: reusable pens and disposable. Reusable insulin pens have cartridges of insulin that are replaced when empty. Disposable insulin pens (used in healthcare settings) come prefilled with insulin and are thrown away when empty.

- Insulin pens are used with pen needles that are sold separately. Insulin pen needles should only be used once.

Preparation

Considerations before device assembly

There are several factors that must be considered before gathering needles, syringes and preparing the medication for administration. These factors include:

Medication

The Five Rights5 – To avoid medication errors, healthcare workers should always verify they are working with the:

- right medication
- right dose
- right patient
- right time
- right route of administration

In addition, a “Sixth” Right also helps to reduce medication errors: the right documentation.

Patient assessment: Reassess patient for any changes in status.

Healthcare workers maintain and follow their facility’s guidelines for aseptic medication preparation and use safety-engineered devices to decrease the risk of a needlestick injury after use and minimize exposure to blood/body fluid.
Devices and equipment

Assembling devices and equipment

In preparation for an injection, it is essential to assemble all the devices and equipment first at a clean work area. This generally includes:

- Medication order
- Alcohol swabs
- Sharps disposal container
- Medication
- Gloves
- Syringe and needle of appropriate size

Preparing the devices and equipment

1. After the equipment has been assembled, perform hand hygiene. Medications are usually supplied as a liquid in a single-dose ampule, vial or multidose vial. A single-dose vial is intended for use in a single patient. Do not administer medications from single-dose vials to multiple patients. A multidose vial contains more than one dose of medication. Multidose vials should be dedicated to a single patient whenever possible. If multidose vials are used, both the needle and syringe used to access the multidose vial must be sterile. Occasionally, they are supplied in a single-dose vial in powder form, which must be reconstituted with either sterile water or saline.

2. Before opening, read the information on the syringe and needle packages. Verify that length and gauge are appropriate. Check that the seals have not been broken; sterility is assured only if the packages are unopened and undamaged.

3. Open the syringe and needle packages (Fig. 1). If the syringe and needle are not one unit, connect the syringe tip to the hub of the needle. Always ensure a secure connection between the needle and syringe. Avoid contamination by not touching the hub of the needle or tip of the syringe.

Proper aseptic technique:

Open the packages by holding the peel tabs, and peel them back only enough to expose the hub of the needle (Fig. 1) or the plunger rod of the syringe (Fig. 2).

Checking the medication

It is essential to:

1. Check medication against the prescription.

2. Check time and date the medication is to be given and that it is for the correct patient.

3. Check medication and diluent (if required) to ensure integrity (i.e., not cloudy or discolored, no particulate matter).

4. Check expiration date and concentration of medication (Fig. 4).

Passive recapping

If recapping is necessary for medication transport, it is preferred that clinicians use a one-handed technique.

The one-handed scoop technique uses the needle itself to pick up the needle shield, and then the shield is pushed up against a hard surface to ensure a tight fit onto the device.

If a hard surface is not available, when the cap covers the needle completely, use the other hand to secure the cap on the needle hub. Be careful to handle the cap at the bottom only (near the hub).

Never use two hands to begin the needle recapping process (Fig. 5).
Filling the syringe

<table>
<thead>
<tr>
<th>Vial</th>
<th>Ampule</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>1.</strong> Read label on vial/ampule, confirm correct medication/fluid and concentration.</td>
<td>Tap head of ampule to unseat any fluid lodged at top.</td>
</tr>
<tr>
<td><strong>2.</strong> After removing vial cap, clean stopper with alcohol swab.</td>
<td>Tap head of ampule to unseat any fluid lodged at top.</td>
</tr>
<tr>
<td><strong>3.</strong> Remove needle shield from a blunt fill needle.</td>
<td>Clean neck with alcohol swab; holding the head of the ampule with swab, snap the neck open. Discard ampule head and swab in sharps collector.</td>
</tr>
<tr>
<td><strong>4.</strong> Draw into the syringe a volume of air equal to the amount of medication/fluid needed. Being careful to avoid touching the needle on any surface (to maintain sterility), insert the needle into the stopper and inject air.</td>
<td>Remove needle shield from a blunt filter needle.</td>
</tr>
<tr>
<td><strong>5.</strong> Hold vial upside down and draw back syringe plunger to correct dosage.</td>
<td>Tilt ampule down, and insert needle tip into opening. Draw back syringe plunger to correct dosage.</td>
</tr>
</tbody>
</table>

**Clean the diluent and medication vial stoppers with an alcohol pad.**

**Draw the diluent into the syringe as you would fill a syringe from a vial.**

**Then inject diluent into powdered medication vial.**

*After passively recapping needle, invert vial until all powder is dissolved. Use caution when inverting vial; some medications should not be agitated vigorously.*

**Clean vial stopper again, uncap needle and pierce stopper a second time to withdraw the prescribed dose.**

<table>
<thead>
<tr>

<th>Ampule</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>6.</strong> Withdraw needle. Passively recap the needle, then remove and dispose properly; attach a hypodermic safety needle of appropriate size.</td>
<td></td>
</tr>
<tr>
<td><strong>7.</strong> Gently tap side of syringe to dislodge air bubbles.</td>
<td></td>
</tr>
<tr>
<td><strong>8.</strong> Gently depress plunger to expel air from syringe.</td>
<td></td>
</tr>
<tr>
<td><strong>9.</strong> Recheck that correct dose has been drawn into syringe.</td>
<td></td>
</tr>
</tbody>
</table>

*Though most diluents come in vials, they will occasionally be packaged in ampules. Please follow instructions accordingly.*
Injection routes
• Intramuscular
• Subcutaneous
• Intradermal

Healthcare workers maintain and follow their facility’s guidelines for aseptic medication preparation and use safety-engineered devices to decrease the risk of a needlestick injury after use and minimize exposure to blood/body fluid.
Before administering an injection (intramuscular, subcutaneous or intradermal), the skin should be cleansed with an antiseptic swab.¹

1. Apply swab at the center of injection site.
2. Rotate outward in a circular direction for about 5 cm (2 inches) around the injection site.
3. Allow to air dry.
Injection routes

Intramuscular (IM):

An injection into the muscle tissue. Large volumes require larger muscles (e.g., vastus lateralis), while smaller volumes (up to 1 mL) can be administered in smaller muscles (e.g., deltoid).

Muscle sites have a good blood supply, which helps the medication to be absorbed more rapidly than by the subcutaneous route. Some of the drugs given by this route are antibiotics, vitamins, vaccines and fertility drugs.5

Intramuscular injections require identification of anatomical markers to assure proper placement. Important note: Infants < 18 months old should not receive an IM injection of > 0.5 mL.

Vastus lateralis muscle: Tolerates volumes up to 5 mL in adults. Maximum volume for ages between 3–13 years is 1.5 mL, 1½–3 years is 1 mL < 1½ years, 0.5 mL. Maximum needle length for children is 1 inch.

Deltoid muscle: Used for volumes of ≤ 1 mL in adults and 0.5 mL in children age > 18 months. Risk: Proximal to the radial nerve and the brachial artery.

Ventrogluteal site: Maximum volume is 3 mL in adults, 2 mL for ages between 6–13 years, 1.5 mL for between 3–6 years, and 1 mL for ages between 1½–3 years. May be the safest and least painful IM injection site.

Dorsogluteal site: Not recommended unless required by drug manufacturer; do not use in children less than 3 years old. Maximum volume is 3 mL in adults, 2 mL for ages between 6–13 years, and 1.5 mL for between 3–6 years. Risks: Proximal to the sciatic nerve, superior gluteal artery and the possibility of injecting medication into the thick layer of subcutaneous tissue over the muscle.

Subcutaneous (SubQ):

An injection into the fatty layer which lies beneath the dermis. This route is used for small volume injections (≤ 1 mL) and when the medication is not likely to irritate or damage the subcutaneous tissue. The blood supply to the subcutaneous tissue is less than in muscle tissue; therefore, the absorption rate is generally slower than with IM injections. This is desirable for some medications (e.g., insulin).

Skin/Subcutaneous thickness: Appropriate needle length and injection technique is dependent on the patient’s skin and subcutaneous fat thickness. Intramuscular injections can be avoided with the use of shorter needles.

Injection sites may have different absorption rates. With animal and human insulins, the abdomen has been shown to have the most rapid absorption, the upper arms intermediate, and the thigh and buttocks the slowest absorption. Rotating insulin injections within a site (at least 1” from previous injection) and using needles only once may avoid the development of lipodystrophy while maintaining a more predictable absorption.

Before you start

Subcutaneous (SubQ):

If used, allow the alcohol from an alcohol swab to dry completely prior to injection.

Following administration, do not apply pressure or massage injection site.

Inject with the needle bevel up.

If a wheal, or bleb, does not appear during administration, the medication is being delivered into the subcutaneous tissue.5

Intradermal (ID):

An injection into the dermis. Only a very small volume of fluid is given (0.1 mL or less).

This route is used to test a patient’s sensitivity to allergens or for tuberculin testing. It is also used for administering local anesthetics.

* Due to the risk of anaphylactic reaction, emergency medication and equipment should be available.

Intradermal (ID):

*  Due to the risk of anaphylactic reaction, emergency medication and equipment should be available.
Vastus lateralis muscle

The vastus lateralis site is located in the lateral middle third of the thigh between the greater trochanter and the knee. When injecting, lift the vastus lateralis muscle away from the bone. Note: The rectus femoris muscle is located in the anterior middle third of the thigh.

Vastus lateralis muscle

Greater trochanter of femur
Middle third of vastus lateralis muscle
Lateral femoral condyle

Deltoid muscle

The thickest part of the deltoit muscle is located 1”–2” (1–3 fingerbreadths) below the lower edge of acromion process of the scapula over the midaxillary line.

Rectus femoris muscle

Anterior superior iliac spine
Iliac crest

Dorsogluteal site

The dorsogluteal site is located above an imaginary line between the greater trochanter and the posterior superior iliac crest. The injection is administered laterally and superior to this imaginary line.

Recommended injection technique (all sites)

4- and 5-mm (.157”–.2”) lengths should be inserted straight-in (90°) without a raised skin fold (skin pinch) in most patients. Young children and lean adults may also require a raised skin fold. 6 mm (.24”) and longer, a raised skin fold should always be used. Thin patients may also require a 45° insertion with 6 mm (.24”) and longer needles.

To avoid accidental needlestick, a raised skin fold should be wide (> 1” between finger and thumb).

Subcutaneous (SubQ):

Intradermal (ID)

Anterior aspect of the forearm
Upper chest
Upper back/Back of arm

Abdomen – avoid injecting within 1–2” around the umbilicus

Upper buttocks
Standard injection procedure

**Intramuscular (IM):**

1. Inject the needle quickly at a 90° angle.
2. Pull back on plunger from 5 to 10 seconds. If blood appears in syringe, remove needle, dispose properly and prepare a new injection.
3. Inject medication slowly.
4. Withdraw needle, and place sterile gauze firmly over site.
5. Engage safety mechanism on needle or syringe.
6. Dispose of properly. Record injection on medication administration record.

**Subcutaneous (SubQ):**

1. Pinch skin. Insert the needle at a 90° or 45° angle.
2. Inject medication slowly.
3. Withdraw needle, and place sterile gauze over site.
4. Engage safety mechanism on needle or syringe.
5. Dispose of properly. Record injection on medication administration record.

If raised skin fold is used, avoid accidental needlesticks by maintaining a distance of > 1” between your finger and thumb. Plus, the raised skin fold must be maintained throughout the injection until the needle is removed from the skin.

**Intradermal (ID):**

1. Spread the skin taut, and insert the needle tip at a 10–15° angle.
2. Inject medication slowly; a small fluid bleb (wheal) forms. If a wheal does not appear, it was administered in the subcutaneous tissue.
3. Withdraw needle, and place sterile gauze over site. Do not massage.
4. Engage safety mechanism on needle or syringe.
5. Dispose of properly. Record injection on medication administration record.

Please refer to hospital guidelines for Z-track procedures.
Each facility has its own policy and method for safe disposal of used needles, syringes, glass vials and ampules. To the extent consistent with a facility’s policies and the availability of proper disposal options, sharps should be disposed of as soon as possible after use. Universal precautions should always be applied.
Safe use and disposal of sharps

Care must be exercised during the use and disposal of sharps. Good practice in the disposal of sharps includes the following key points:

- All staff must dispose of sharps correctly.
- The person using the sharp is responsible for disposing of it in an approved sharps disposal container. The facility is responsible for ensuring the disposal of the container.
- The sharps container should be at the place where sharps are used so that they can be disposed of immediately after use.
- Sharps containers should NEVER be overfilled.
- Used needles should NEVER be recapped, cut or bent.
- All incidents or accidents involving needlestick injuries and/or accidents involving body fluids should be recorded and reported in line with local policies.

Selecting, evaluating and using sharps disposal containers

Safety performance criteria for sharps disposal containers are divided into four areas:

1. **Functional**: Sharps disposal containers should be durable, leak resistant and puncture resistant.

2. **Accessible**: Sharps disposal containers must be accessible to workers who use, maintain or dispose of sharps devices. This includes sufficient number, sufficient container volume and safe access to the disposal opening on individual containers. Other important factors include convenient placement and (if necessary) portability of containers within the workplace.

3. **Visible**: Sharps disposal containers should be visible to the workers who must use them. Container fill status and warning labels are also important visibility criteria.

4. **Accommodative**: The sharps disposal container should accommodate the user, the facility and the environment.
References

In November 2000, the Needlestick Safety and Prevention Act (NSPA) was signed into law, requiring that healthcare providers comply with a variety of actions designed to improve the occupational safety of clinicians. The law became effective in April 2001.

The law requires employers to evaluate, select and use safety-engineered medical devices to eliminate or minimize occupational exposure to bloodborne pathogens. This would include all devices used for skin injections. Moreover, the law intends that frontline healthcare workers are to be part of the evaluation and selection process.

To better prepare clinicians to participate in the process, and to provide a safer work environment, the following pages are designed to explain the differences in the types of safety-engineered technologies available for hypodermic syringes and needles.

In addition to converting conventional devices to those with safety-engineered features, there are other steps clinicians can take to minimize the potential for needlesticks:

- Eliminate the unnecessary use of needles on “needleless” IV systems
- Implement safety-engineered prefilled syringes when possible
Safety-engineered device technologies

Retracting syringe
- Syringe-based safety feature
- User retracts needle into syringe after use
- Devices are spring-activated or manually retracted
- Available with removable needles or permanently attached needles

Shown: BD Integra™ Syringe

Shielding needle
- Needle-based safety feature
- Can be used with any conventional syringe
- Safety mechanism slides over needle after use
- Devices have assisted or fully manual activation
- Available with removable needles and permanently attached needles

Shown: BD SafetyGlide™ Needle

Pivoting needle
- Needle-based safety feature
- Can be used with any conventional luer lock syringe
- Safety shield pivots around hub to lock onto needle
- Fully manual activation
- Available with removable needles

Shown: BD Eclipse™ Needle

Sliding shield syringe
- Syringe-based safety feature
- Sleeve slides over needle and locks
- Fully manual activation
- Available with removable needles or permanently attached needles

Shown: BD Safety-Lok™ Syringe
