

BD Medical – Diabetes Care pharmacy catalog

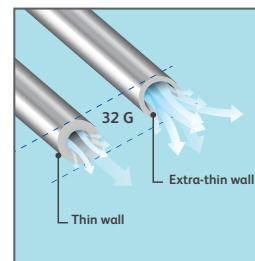

Introduce your patients to BD Nano™ Ultra-Fine™ Pen Needles today

Recent recommendations published in *Mayo Clinic Proceedings* state that the shortest pen needle available (*currently 4 mm*) is the safest for all patient categories.¹

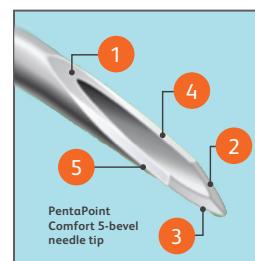

Only BD Nano™ Pen Needles combine two technologies for an optimized injection experience^{2,3}

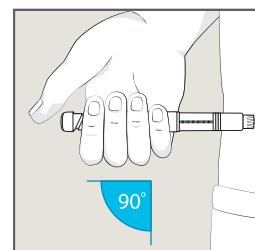

EasyFlow™ Technology

Allows for up to 149% higher insulin flow and less thumb force when performing an injection^{2*}

PentaPoint™ Comfort

Requires less penetration force for a more comfortable injection^{3†}

BD Nano™ Pen Needles

Allow for a one-handed, no-pinch-up technique injection,[‡] providing access to more injection sites and facilitating proper site rotation⁴

Covered by most health plans at the preferred co-pay, including Medicare Part D[§]

Compatible with leading pen injection devices⁵

*Compared to regular and thin walled comparator pen needles

† Compared to 3-bevel needles

‡ Consult the Instructions for Use and/or your healthcare provider about proper injection technique.

§ Co-pays and preferred status vary by plan.

Introduce your patients to BD Veo™ Insulin Syringes with BD Ultra-Fine™ 6 mm needle today

- Our shortest insulin syringe needle available—in line with recent clinical recommendations¹
- Approximately 8x-lower risk of intramuscular (IM) injection^{4*}
- 6 mm x 31G needle designed for a more comfortable injection^{1†}

Per recent recommendations published in *Mayo Clinic Proceedings*:

"The shortest insulin syringe needle available (currently 6 mm[§]) is the safest for all patient categories."¹

Covered by most health plans at the preferred co-pay, including Medicare Part D[†]

Most patients prefer BD Veo™ Insulin Syringes with BD Ultra-Fine™ 6 mm needle over longer needles⁶

Select barrel capacity based on largest daily insulin dose

Choose the insulin syringe capacity based on the patient's largest daily insulin dose

Where possible, keeping the barrel size at least five units larger than your patient's largest daily dose helps minimize both **plunger pull-out** and potential medication waste.

Dosage units	Recommended insulin syringe capacity
Up to 25 units	3/10 mL (Half-unit scale) or 3/10 mL (one-unit scale)
26–45 units	1/2 mL
46–100 units	1 mL

Three boxes of BD Veo Insulin Syringes with BD Ultra-Fine 6 mm needle are shown side-by-side. The top box is purple and labeled '3/10 mL'. The middle box is blue and labeled '1/2 mL'. The bottom box is green and labeled '1 mL'. Each box has the number '6' and 'mm' on it.

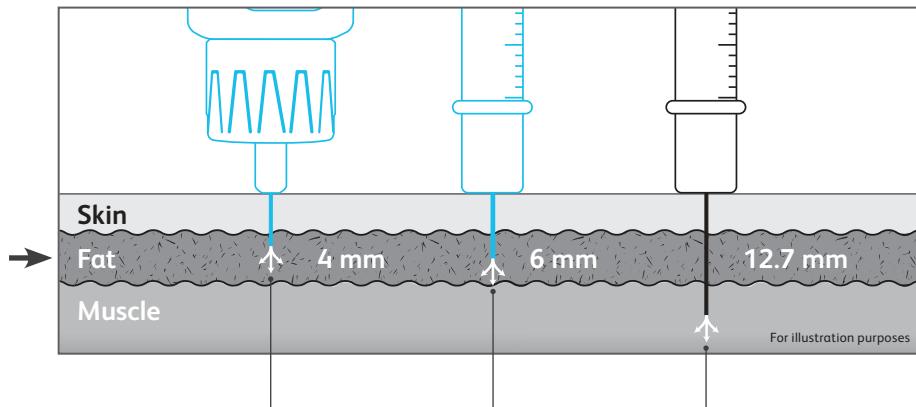

BD® Insulin Syringes with BD Ultra-Fine™ needle are available in all barrel capacities

* Compared to a 12.7 mm needle, when inserted at 90° without a pinch-up technique in an adult population.

† Co-pays and preferred status vary by plan.

§ Excluding safety syringes.

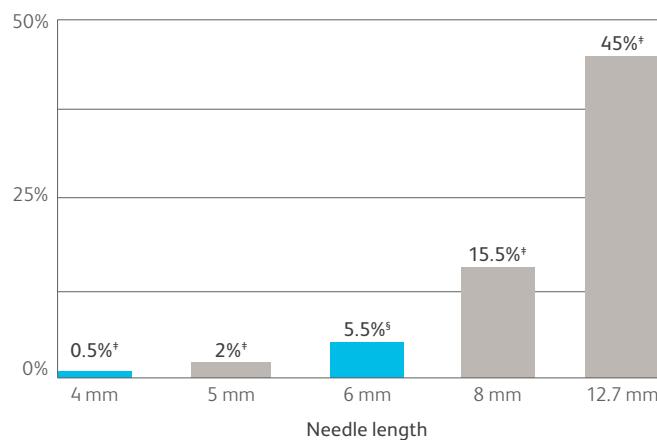

It's important for patients to inject with the **shortest** needles available

- Insulin is meant to be injected into the fat layer just below the skin for consistent absorption¹
- Shorter needle lengths (*6 mm or less*) decrease the risk of injecting into the muscle.^{1,4*}

- If patients inject into the muscle, the insulin may be absorbed inconsistently, which may lead to low blood sugar and poor glycemic control.¹

Calculated probability of IM injection by needle length^{4†}

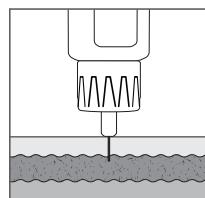

* Compared to longer needles.

† A needle inserted at 90° without a pinch-up technique in an adult population.

‡ Rounded up to the nearest half percent.

§ Rounded down to the nearest half percent.

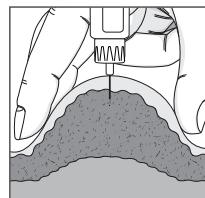

Counsel patients on injection technique based on needle length

Shorter needle length

Patients don't need to use a pinch-up technique. Inject at 90° (*straight in*) to the skin.^{4*}

4 mm and 5 mm

Longer needle length

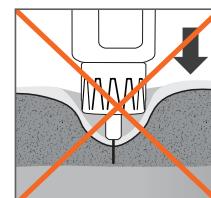

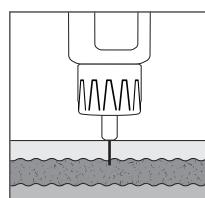

Patients should use a pinch-up technique. Inject at 90° (*straight in*) to the pinch-up.⁴

6 mm, 8 mm and 12.7 mm

Proper injection technique matters

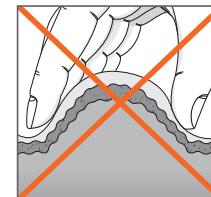

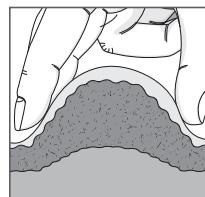

No pinch-up technique

When no pinch-up technique is used – explain to patients the importance of proper needle insertion force technique.¹¹

A correct no pinch-up technique requires light pressure when inserting the needle into the skin, just touching the pen needle base to the skin.

Pinch-up technique

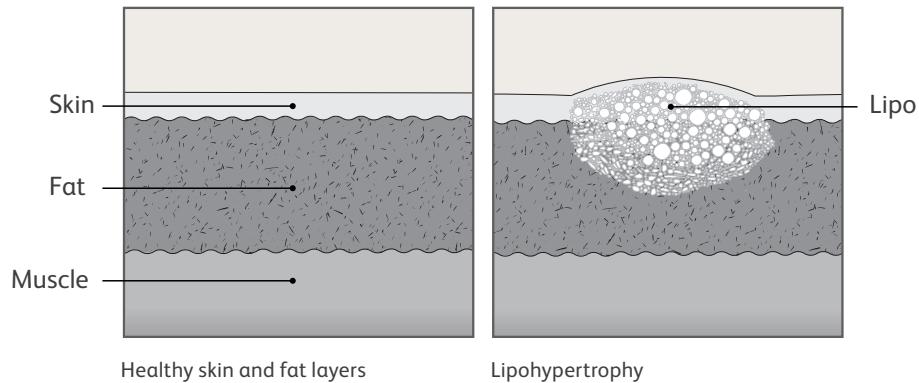

A correct pinch-up is made by lifting the skin with the thumb and index finger. If the skin is lifted using the whole hand, muscle may be lifted as well as subcutaneous tissue, which can lead to IM injections.¹

The pinch-up should be held until the injection is complete and the needle has been removed from the skin.¹

* Consult the Instructions for Use and/or your healthcare provider about proper injection technique.

Lipohypertrophy (*lipo*) and insulin injections

Lipo is one of the most common complications of insulin injections.

In one study, almost 2/3 of all people who inject insulin had some degree of lipo.⁷

76% of type 1 diabetes patients had lipo

56% of type 2 diabetes patients had lipo

Lipo can affect diabetes management

In a study,
22% or more
than 1/5 of the insulin injected
into lipo was **not absorbed into**
the body⁸

In a study, nearly
40%
of people with lipo experienced
unexplained hypoglycemia compared
to 6% of people without lipo⁷

What can lead to lipo?

A large international survey of people who inject insulin found that there are three independent risk factors that make people more likely to develop lipo. Two of the most common are:^{9*}

- Not rotating injection sites correctly
- Reusing needles

* No causal link has been established between these factors and the development of lipohypertrophy

Encourage your patients to replace their needle every time they inject

You can help your patients reduce their risk of developing lipo by reminding them to:¹

1. Replace their needle every time they inject
2. Rotate their injection sites

Insulin syringes and pen needles are designed for single use and should only be used once—they are no longer sterile after use¹

In a study, the more patients reused their needles, the more likely they were to develop lipo.⁷

A recent study of structured insulin injection technique training - including counseling on:

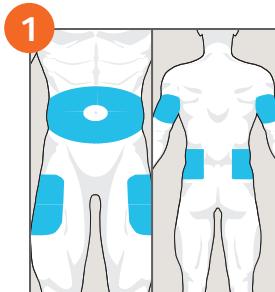

- using a shorter needle length
- using a new needle with each injection
- site rotation

resulted in an A1c reduction of 1% at 6 months.¹⁰

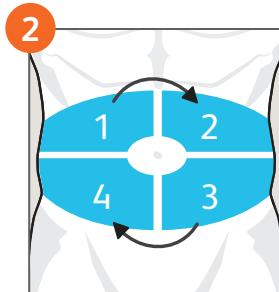

Encourage your patients to follow proper injection site rotation

It's important to rotate injections *within* each area and *between* areas on a regular basis¹

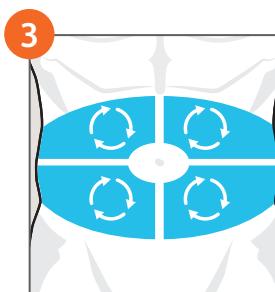

The abdomen, thighs, arms and buttocks are generally recommended injection areas.

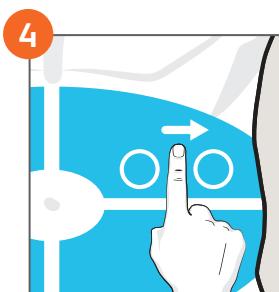

Choose an area.

Divide that area into four sections.

Select an injection site in a section to start injecting. Use one section per week.

Inject one finger width away from your last injection.

Patients should always safely dispose of their needles¹

- After use, needles should be disposed of immediately. Pen needles should not be left attached to the pen, and should not be recapped.
- Always dispose of sharps in a medical sharps container.
- Used sharps should never be discarded directly into household or public trash.
- Family members, caregivers and service providers (e.g., child care and sanitation workers) should be taught about safe sharps disposal.

Helping your patients better manage their diabetes

Sharing your knowledge of proper insulin injection technique is invaluable for patients with diabetes. Just as important is the trust you've built with your patients. At BD, we believe your knowledge and relationships are the foundation for persistent therapy adherence. This is why we are committed to supporting you and the patients you serve with innovative products and services that help improve the comfort and satisfaction of every patient's experience.
